PROJECT PRESENTATION ON

Secure Decentralized Data Storage for Supply Chain

SUBMITTED BY

KC Muhamed Naseem Bin Najeeb

III Year BCA

(Artificial Intelligence, Cloud Computing and DevOps)With IBM&TCS

REGISTER NUMBER: 23BCAICD043

UNDER THE GUIDANCE OF

Ms.Manjula

[Faculty Guide]

INDUSTRY IBM MENTOR: Sumit Kumar Shukla

DEPARTMENT OF COMPUTER SCIENCE

IN PARTIAL FULFILMENT OF THE REQUIREMENT FOR THE AWARD OF THE DEGREE OF

BACHELOR OF COMPUTER APPLICATIONS

MAY 2026

CERTIFICATE

This is to certify that the project report entitled "Blockchain-Based Supply Chain Management System" submitted by KC MUHAMED NASEEM BIN NAJEEB Register No: 23BCAICD043 of IIIrd YEAR BCA (Cloud Computing & Devops), Yenepoya Institute of Arts, Science, Commerce and Management, Mangalore, is a bonafide record of the project work carried out by the student under our guidance and supervision during the academic year 2023–2026.

This project has been prepared as part of the IBM SkillsBuild Internship Programme and fulfils the requirement for the partial fulfilment of the degree of Bachelor of Computer Applications (BCA) of Yenepoya (Deemed to be University), Mangalore.

Internal Guide	**Head of Department**
[MS.MANJULA] Dept. of Computer Science	[Dr.Rathnakara Shetty P] Dept. of Computer Science

DECLARATION

I, KC MUHAMED NASEEM BIN NAJEEB, a student of IIIrd YEAR BCA (Cloud Computing & Devops), Register No: 23BCAICD043, Yenepoya Institute of Arts, Science, Commerce and Management, Mangalore, hereby declare that this project report entitled "Blockchain-Based Supply Chain Management System" is the original work done by me under the guidance of Ms.Manjula, Department of Computer Science.

This report has not been submitted partially or fully to any other university or institution for the award of any degree or diploma. All the information and data presented in this report are true and accurate to the best of my knowledge and belief.

The project was developed as part of the IBM SkillsBuild Internship Programme 2023–2026. I take full responsibility for the content of this report.

Place:Mangalore
Date:May 2026

KC MUHAMED NASEEM BIN NAJEEB
III year BCA

ACKNOWLEDGEMENT

I express my sincere gratitude and heartfelt thanks to all those who have contributed to the successful completion of this project.

I am deeply grateful to Principal of Yenepoya Institute of Arts, Science, Commerce and Management, for providing an excellent academic environment and necessary infrastructure for conducting this project.

I would like to extend my sincere thanks to Vice Principal, for the continuous encouragement and support extended throughout the academic year.

I am immensely grateful to Head of the Department of Computer Science, for the invaluable guidance, motivation, and support provided at every stage of this project.

I express my deepest appreciation to my Internal Guide, Ms.Manjula Assistant Professor, Department of Computer Science, whose expert advice, constructive feedback, and patient mentorship made this project possible.

I also extend my sincere thanks to my Industry Mentor from IBM for providing SkillsBuild Programme, for the industry insights, technical guidance, and professional mentorship provided during this internship.

I am grateful to all the faculty members of the Department of Computer Science for their encouragement and academic support throughout the course.

Finally, I thank my family and friends for their constant support, encouragement, and motivation throughout the completion of this project.

KC MUHAMED NASEEM BIN NAJEEB

EXECUTIVE SUMMARY

Background

This project presents the design, development, and implementation of a Blockchain-Based Supply Chain Management System. The system leverages Python's cryptographic capabilities to simulate an immutable ledger that records every event in a product's journey from raw material sourcing to final delivery.

Aim

The primary aim of this project is to demonstrate how blockchain technology can be applied to real-world supply chain scenarios to prevent data tampering, ensure transparency, and build trust among stakeholders. The system simulates a five-block chain tracking a product through Chennai, Coimbatore, Bangalore, and Mumbai.

Technologies

The project is built using Python 3.14, the hashlib library for SHA-256 cryptographic hashing, and the datetime module for timestamping. The development environment used was Visual Studio Code on a Windows platform.

Hardware Architecture

The system runs on a standard personal computer with minimum hardware requirements including a dual-core processor, 4 GB RAM, and 100 MB disk space.

Software Architecture

The software architecture consists of two primary classes: the Block class and the Blockchain class. The Block class encapsulates all data, timestamps, and cryptographic hashes. The Blockchain class manages chain operations including appending and validation.

System

The system successfully demonstrates blockchain immutability by appending five supply chain events and validating the chain. The tamper detection mechanism correctly identifies modified blocks, returning a False validation status when any data is altered.

1. BACKGROUND

1.1 Introduction to Blockchain

Blockchain is a form of distributed ledger technology (DLT) that records transactions across many computers in such a way that the records cannot be altered retroactively without the alteration of all subsequent blocks and the consensus of the network. Originally conceptualized by Satoshi Nakamoto in 2008 as the underlying technology for Bitcoin, blockchain has evolved far beyond cryptocurrency into diverse fields such as supply chain management, healthcare, finance, and smart contracts.

A blockchain is essentially a chain of blocks, where each block contains a set of data, a timestamp, and a cryptographic hash of the previous block. This structure creates an inherent tamper-evidence mechanism: if any block is modified, all subsequent blocks become invalid because their stored previous hashes no longer match. This property, known as immutability, is one of the cornerstone features that makes blockchain suitable for trustless data management.

Key properties of blockchain technology include:

- Decentralization: No single entity controls the chain; data is distributed across nodes.
- Immutability: Once data is recorded, it is practically impossible to alter without detection.
- Transparency: All participants can view and verify the chain's contents.
- Security: Cryptographic hashing ensures data integrity at every block.
- Consensus: Agreement mechanisms ensure all nodes validate new entries.

In the context of this project, a simplified single-node blockchain is implemented to focus on demonstrating the core principles of immutability and tamper detection within a supply chain scenario. This approach is pedagogically sound for understanding how enterprise blockchains such as Hyperledger Fabric or IBM Blockchain Platform operate at their fundamental level.

1.2 Supply Chain Management Overview

Supply Chain Management (SCM) refers to the active management of supply chain activities to maximize customer value and achieve a sustainable competitive advantage. A supply chain encompasses all activities from product creation — raw material sourcing, manufacturing, packaging, and warehousing — through to delivery to the end consumer.

Traditional supply chains face several critical challenges that compromise efficiency, transparency, and trust among stakeholders:

- Data Silos: Each organization in the supply chain maintains its own records, leading to inconsistencies and lack of visibility.
- Fraud and Counterfeiting: Without a shared, verified record, fraudulent activities such as the substitution of materials or falsification of quantities can go undetected.
- Lack of Traceability: When a product defect or contamination occurs, tracing the origin through multiple fragmented systems is costly and time-consuming.
- Inefficient Reconciliation: Disputes between suppliers, manufacturers, and retailers require expensive manual reconciliation processes.
- Paper-Based Processes: Many supply chains still rely on paper documentation, which is prone to loss, damage, and alteration.

Blockchain-based supply chain solutions address these challenges by providing a shared, immutable ledger that all authorized participants can access. Every event — from raw material sourcing to final delivery — is recorded as a block on the chain, creating a permanent, auditable trail of the product's journey. This enables instant traceability, transparent auditing, and automated dispute resolution.

Major industry players including IBM, Walmart, Maersk, and De Beers have implemented blockchain supply chain solutions. IBM's Food Trust platform, for instance, uses Hyperledger Fabric to track food safety across agricultural supply chains, enabling rapid recall processes that previously took days to complete in minutes.

1.3 Problem Statement

The traditional supply chain management systems are centralized, siloed, and lack the transparency required for effective stakeholder trust and accountability. Data recorded at one stage of the supply chain is rarely visible to other participants, creating opportunities for fraud, error, and inefficiency. Specifically, the following problems have been identified:

1. Quantity Fraud: Suppliers may report different quantities at different stages of the supply chain, with no mechanism to detect discrepancies. For example, if 500 units of raw material are sourced but only 480 units reach the manufacturing stage, the 20-unit discrepancy may be hidden by falsifying records.
2. Data Tampering: Centralized records are vulnerable to unauthorized modification by malicious actors, including both internal employees and external attackers.
3. Lack of Real-Time Visibility: Supply chain managers often lack real-time visibility into the status of goods, leading to inefficient inventory management and delayed responses to disruptions.
4. Trust Deficit: Multiple parties in a supply chain — suppliers, manufacturers, warehouses, and retailers — often do not fully trust each other's records, leading to costly verification processes.
5. Audit Complexity: Regulatory compliance and audit processes are time-consuming and expensive due to fragmented record-keeping.

This project proposes a blockchain-based solution that addresses these challenges by implementing an immutable, tamper-evident ledger that records every supply chain event with cryptographic integrity.

2. AIM AND OBJECTIVES

The primary aim of this project is to design and implement a Blockchain-Based Supply Chain Management System that demonstrates the principles of cryptographic immutability and tamper detection using Python. The project serves as both a functional prototype and an educational demonstration of how blockchain technology can secure supply chain records.

2.1 Primary Aim

To develop a Python-based blockchain simulation that records supply chain events as immutable, cryptographically linked blocks and demonstrates real-time tamper detection when any block's data is modified.

2.2 Specific Objectives

- To implement a Block class that encapsulates supply chain event data, timestamps, and SHA-256 cryptographic hashes.
- To implement a Blockchain class that manages the chain of blocks, including block appending and chain validation.
- To simulate a realistic supply chain scenario spanning four stages: raw material sourcing, manufacturing, warehousing, and retail delivery.
- To demonstrate the immutability property by showing that any modification to block data is instantly detected by the is_valid() function.
- To provide clear, readable console output that illustrates the chain structure and tamper detection results.
- To design the system in a modular, extensible manner that can be scaled to include additional features such as digital signatures, peer-to-peer networking, and a graphical interface.

2.3 Learning Outcomes

- Understanding of fundamental blockchain data structures including hash pointers and linked block chains.
- Practical application of SHA-256 cryptographic hashing using Python's hashlib library.
- Proficiency in Python object-oriented programming for real-world system design.
- Appreciation of how cryptographic security principles are applied in distributed ledger systems.
- Exposure to IBM SkillsBuild industry training methodologies and professional software development practices.

3. TECHNOLOGIES USED

The project leverages a carefully selected set of technologies chosen for their suitability to the blockchain domain, their stability, and their widespread industry use. All technologies used are free and open-source.

3.1 Python 3.14

Python is the primary programming language used in this project. Python 3.14, the version used, provides an expressive, readable syntax ideal for implementing object-oriented blockchain structures. Python's extensive standard library, particularly hashlib and datetime, eliminates the need for third-party dependencies, making the project self-contained and easily reproducible.

Key Python features utilized in this project include:

- Object-Oriented Programming (OOP): Classes and instance methods are used to model blocks and the blockchain.
- String formatting: f-strings are used for clean, readable console output.
- List management: The chain is stored as a Python list, enabling efficient append and traversal operations.

3.2 SHA-256 Cryptographic Hashing

SHA-256 (Secure Hash Algorithm 256-bit) is a member of the SHA-2 family of cryptographic hash functions, designed by the United States National Security Agency (NSA) and published by the National Institute of Standards and Technology (NIST). It is the same hashing algorithm used by Bitcoin and many enterprise blockchain platforms.

SHA-256 produces a fixed 256-bit (64 hexadecimal character) output digest from any input. Its cryptographic properties make it ideal for blockchain applications:

- Deterministic: The same input always produces the same hash.

- Avalanche Effect: Even a single character change in the input produces a completely different hash.
- Pre-image Resistance: It is computationally infeasible to reverse a hash back to its original input.
- Collision Resistance: It is computationally infeasible to find two inputs that produce the same hash.

In this project, SHA-256 is applied to a concatenation of block index, timestamp, data, and previous hash to generate each block's unique fingerprint.

3.3 hashlib Library

The hashlib library is part of Python's standard library and provides a common interface to many secure hash and message digest algorithms. In this project, hashlib.sha256() is used to compute the SHA-256 hash of block data. The .encode() method converts string data to bytes before hashing, as required by the algorithm.

3.4 datetime Module

Python's datetime module is used to generate accurate timestamps for each block at the moment of its creation. Using datetime.datetime.now() ensures that each block carries a precise, unique timestamp that contributes to the uniqueness of its hash, further strengthening tamper evidence.

3.5 Visual Studio Code IDE

Visual Studio Code (VS Code) was used as the primary Integrated Development Environment (IDE). VS Code's Python extension provides syntax highlighting, auto-completion, integrated debugging via debugpy, and an integrated terminal, making it an ideal environment for developing and testing the blockchain implementation.

Technology	Version	Purpose	License
Python	3.14	Primary programming language	PSF License
hashlib	Standard Library	SHA-256 cryptographic hashing	PSF License

Technology	Version	Purpose	License
datetime	Standard Library	Block timestamp generation	PSF License
Visual Studio Code	Latest	Development IDE	MIT License
debugpy	Latest	VS Code debugging launcher	MIT License

4. HARDWARE ARCHITECTURE

The Blockchain-Based Supply Chain Management System is implemented as a standalone software simulation that runs on a standard personal computer. The hardware requirements are minimal because the system performs computational hash calculations rather than network communication or database operations. No specialized hardware such as servers, ASICs, or network infrastructure is required for the simulation.

4.1 Minimum Hardware Requirements

Component	Minimum Specification	Recommended Specification
Processor	Intel Core i3 / AMD equivalent (2.0 GHz dual-core)	Intel Core i5 or higher
RAM	4 GB DDR4	8 GB DDR4
Storage	100 MB free disk space	1 GB SSD free space
Operating System	Windows 10 / Ubuntu 20.04 / macOS 11	Windows 11 / Ubuntu 22.04
Display	1024 x 768 resolution	1920 x 1080 resolution
Network	Not required (standalone)	Optional for future extension

4.2 Development Environment Hardware

The project was developed and tested on the following hardware configuration:

- Processor: Intel Core i5 / AMD Ryzen series
- RAM: 8 GB DDR4
- Storage: 256 GB SSD
- Operating System: Windows 10/11
- Python Runtime: Python 3.14 (64-bit)

4.3 Hardware Architecture for Real-World Deployment

While this project is a simulation running on a single machine, a real-world blockchain supply chain deployment would require a distributed hardware architecture. Each organization in the supply chain (supplier, manufacturer, warehouse, retailer) would run a node on their own server infrastructure. The nodes would communicate via a peer-to-peer network protocol, with consensus algorithms ensuring agreement on the valid state of the chain. IBM's Blockchain Platform typically deploys such nodes on cloud infrastructure such as IBM Cloud, AWS, or Azure Kubernetes Service.

5. SOFTWARE ARCHITECTURE

The software architecture of the Blockchain-Based Supply Chain Management System follows an object-oriented design pattern with two primary classes: Block and Blockchain. The architecture is intentionally minimalist to clearly demonstrate core blockchain principles without unnecessary complexity.

5.1 System Architecture Diagram

The high-level system architecture can be described as a layered structure:

- Layer 1 – Application Layer: The main program (blockchain.py) orchestrates all operations, creating the blockchain, adding blocks, and initiating validation.
- Layer 2 – Blockchain Layer: The Blockchain class manages the chain, stores blocks in a list, and provides chain-level operations (add_block, is_valid).
- Layer 3 – Block Layer: The Block class encapsulates individual block data including the index, timestamp, data payload, previous hash, and current hash.
- Layer 4 – Cryptographic Layer: The hashlib.sha256() function provides the cryptographic foundation, converting block data into unique fixed-length fingerprints.

5.2 Block Structure

Each block in the chain contains the following attributes:

Attribute	Type	Description	Example Value
index	Integer	Sequential block number	0, 1, 2, 3, 4
timestamp	String	Datetime of block creation	2026-04-26 16:19:57
data	Dict / String	Supply chain event payload	{event: Raw Materials...}
previous_hash	String (64 hex)	Hash of the preceding block	39f66d8cd9a82ed8...
hash	String (64 hex)	SHA-256 hash of this block	a9af37b6091843aa...

5.3 Chain Linkage Mechanism

The chain is secured through a hash pointer mechanism. When a new block is created, it receives the hash of the immediately preceding block as its previous_hash attribute. Its own hash is then computed from all its attributes, including this previous_hash value. This creates a cryptographic dependency chain:

```
Block 0:  prev_hash = '0'          →  hash = SHA256(0 + data0 + ts0 +
'0')       = H0
Block 1:  prev_hash = H0           →  hash = SHA256(1 + data1 + ts1 +
H0)          = H1
Block 2:  prev_hash = H1           →  hash = SHA256(2 + data2 + ts2 +
H1)          = H2
Block 3:  prev_hash = H2           →  hash = SHA256(3 + data3 + ts3 +
H2)          = H3
Block 4:  prev_hash = H3           →  hash = SHA256(4 + data4 + ts4 +
H3)          = H4
```

If an attacker modifies data2, the recomputed hash of Block 2 changes to H2'. Block 3's stored previous_hash is still H2 (the old value), creating a detectable mismatch. This cascade effect means a single modification corrupts all subsequent chain links, making the tampering immediately detectable.

6. SYSTEM REQUIREMENTS

6.1 Functional Requirements

Functional requirements define what the system must do — its behaviors, features, and operations. The following functional requirements were identified and implemented:

FR ID	Requirement	Priority	Status
FR-01	System shall create a Genesis Block as the first block in the chain	High	Implemented
FR-02	System shall accept new supply chain event data and append it as a new block	High	Implemented
FR-03	System shall compute SHA-256 hash for each block on creation	High	Implemented
FR-04	System shall store the previous block's hash in each new block	High	Implemented
FR-05	System shall provide a chain validation function (is_valid)	High	Implemented
FR-06	System shall detect hash mismatches in any block	High	Implemented
FR-07	System shall detect broken chain links between consecutive blocks	High	Implemented
FR-08	System shall display all block details in readable console output	Medium	Implemented
FR-09	System shall identify and report the specific block where tampering occurred	Medium	Implemented
FR-10	System shall support supply chain event data as dictionary payloads	Medium	Implemented

6.2 User Requirements

User requirements describe the needs and expectations of the end users interacting with the system. In a real-world supply chain blockchain deployment, users would include supply chain managers, logistics coordinators, auditors, and IT administrators.

- UR-01: Users shall be able to record a new supply chain event (e.g., goods received, manufactured, shipped) by providing event data.
- UR-02: Users shall be able to view the complete history of all supply chain events in chronological order.

- UR-03: Users shall be able to trigger a chain validation check at any time to verify the integrity of all records.
- UR-04: Users shall be informed of any detected tampering, including the specific block number where the integrity was compromised.
- UR-05: Users shall be able to view the cryptographic hash of each block to manually verify data integrity.
- UR-06: Auditors shall be able to access a read-only view of the complete chain for compliance verification.
- UR-07: Supply chain managers shall be able to track the quantity of goods at each stage and identify discrepancies.

6.3 Environmental Requirements

Environmental requirements specify the conditions under which the system must operate, including software dependencies, runtime environments, and operational constraints.

Requirement	Specification
Operating System	Windows 10/11, Ubuntu 20.04+, macOS 11+
Python Version	Python 3.8 or higher (tested on Python 3.14)
Required Libraries	hashlib (standard library), datetime (standard library)
Third-Party Dependencies	None — fully self-contained
Development IDE	Visual Studio Code with Python extension
Execution Environment	Command line terminal or VS Code integrated terminal
Network Connectivity	Not required for standalone simulation
Disk Space	Minimum 100 MB free space for Python installation

7. DESIGN AND ARCHITECTURE

7.1 Class Design

The system is designed using two Python classes following object-oriented design principles. The class design emphasizes separation of concerns: the Block class is responsible for individual record integrity, while the Blockchain class is responsible for chain management and validation.

7.1.1 Block Class

The Block class represents a single record in the blockchain. Its responsibilities include:

- Storing all attributes of a supply chain event including index, timestamp, data, previous hash, and current hash.
- Computing its own SHA-256 hash upon instantiation via the calculate_hash() method.
- Exposing calculate_hash() for re-computation during validation to detect data changes.

7.1.2 Blockchain Class

The Blockchain class manages the collection of blocks. Its responsibilities include:

- Initializing the chain with the Genesis Block.
- Appending new blocks with correct chain linkage via the add_block() method.
- Validating the entire chain via the is_valid() method, checking both hash consistency and chain linkage.

7.2 Data Flow Diagram

The data flow through the system when a new supply chain event is recorded proceeds as follows:

6. Supply chain event data is prepared as a Python dictionary (e.g., {event: 'Raw Materials Sourced', location: 'Chennai', qty: 500}).

7. The add_block() method retrieves the last block in the chain and extracts its hash.
8. A new Block object is created with the event data and the previous block's hash.
9. The Block constructor calls calculate_hash(), concatenating index + timestamp + data + previous_hash and computing their SHA-256 digest.
10. The new block is appended to the Blockchain's chain list.
11. Upon validation, is_valid() iterates through all blocks, re-computes each block's hash, and verifies chain links.

7.3 Entity Relationship Diagram

The conceptual entity relationship of the blockchain can be represented as:

```
┌──────────────────────────────────────────────────────────────┐
│                        BLOCKCHAIN                            │
│   chain (List[Block])                                        │
│   + __init__()  → creates Genesis Block                      │
│   + add_block(data)  → appends Block to chain                │
│   + is_valid()  → validates all hashes and links             │
└──────────────────────────────────────────────────────────────┘
                            │
                            │ contains 1..n
┌──────────────────────────▼───────────────────────────────────┐
│                          BLOCK                               │
│   index: int                                                 │
│   timestamp: str                                             │
│   data: dict|str                                             │
│   previous_hash: str                                         │
│   hash: str                                                  │
│   + calculate_hash()  → SHA-256 fingerprint                  │
└──────────────────────────────────────────────────────────────┘
```

8. IMPLEMENTATION

This chapter presents the complete implementation of the Blockchain-Based Supply Chain Management System with detailed code explanations and annotations. The implementation is contained in a single Python file, blockchain.py, consisting of approximately 80 lines of well-commented code.

8.1 Block Class Implementation

The Block class is the fundamental building unit of the blockchain. Below is the complete implementation with line-by-line explanation:

```
import hashlib
import datetime

class Block:
    def __init__(self, index, data, previous_hash):
        self.index         = index
        self.timestamp     = str(datetime.datetime.now())
        self.data          = data
        self.previous_hash = previous_hash
        self.hash          = self.calculate_hash()

    def calculate_hash(self):
        text = str(self.index) + self.timestamp + str(self.data) +
self.previous_hash
        return hashlib.sha256(text.encode()).hexdigest()
```

Line-by-line explanation:

- import hashlib: Imports Python's built-in cryptographic hashing library. This library provides the SHA-256 algorithm.
- import datetime: Imports the datetime module for generating accurate timestamps.
- self.index: Stores the sequential position of the block in the chain (0 for Genesis, 1 for first event, etc.).
- self.timestamp: Records the exact date and time of block creation as a string (e.g., '2026-04-26 16:19:57.706988').

- self.data: Stores the supply chain event payload. This can be a string (for the Genesis block) or a Python dictionary (for all event blocks).
- self.previous_hash: Stores the hash of the preceding block, creating the cryptographic chain link. The Genesis block uses '0' as there is no predecessor.
- self.hash = self.calculate_hash(): Automatically computes the block's hash on instantiation, ensuring every block has a valid hash from the moment it is created.
- calculate_hash(): Concatenates all block attributes into a single string, encodes it to bytes, and computes the SHA-256 digest, returning a 64-character hexadecimal string.

8.2 Blockchain Class Implementation

The Blockchain class manages the entire chain, providing methods to add blocks and validate the chain's integrity:

```
class Blockchain:
    def __init__(self):
        self.chain = [Block(0, 'Genesis Block - Supply Chain Start',
'0')]

    def add_block(self, data):
        previous_block = self.chain[-1]
        new_block = Block(len(self.chain), data, previous_block.hash)
        self.chain.append(new_block)

    def is_valid(self):
        for i in range(1, len(self.chain)):
            curr = self.chain[i]
            prev = self.chain[i - 1]
            if curr.hash != curr.calculate_hash():
                return False
            if curr.previous_hash != prev.hash:
                return False
        return True
```

Detailed explanation of the Blockchain class:

- __init__: Initializes the chain as a Python list containing the Genesis Block. The Genesis Block has index 0, 'Genesis Block - Supply Chain Start' as its data, and '0' as its previous_hash since no block precedes it.

- add_block(data): Retrieves the last block in the chain (self.chain[-1]), creates a new Block with the provided data and the previous block's hash as its previous_hash, and appends it to the chain list.
- is_valid(): Iterates through all blocks starting from index 1. For each block, it performs two checks: (1) it recomputes the block's hash and compares it to the stored hash to detect data modification; (2) it compares the block's stored previous_hash to the actual hash of the preceding block to detect chain link breaks.

8.3 Supply Chain Events

The main program creates the blockchain and adds four supply chain events representing the complete journey of goods from raw material sourcing to retail delivery:

```
sc_chain = Blockchain()

sc_chain.add_block({
    "event": "Raw Materials Sourced",
    "location": "Chennai",
    "qty": 500
})
sc_chain.add_block({
    "event": "Manufacturing Complete",
    "location": "Coimbatore",
    "qty": 480
})
sc_chain.add_block({
    "event": "Warehouse Stored",
    "location": "Bangalore",
    "qty": 480
})
sc_chain.add_block({
    "event": "Delivered to Retailer",
    "location": "Mumbai",
    "qty": 475
})
```

The supply chain scenario tracks a product through four Indian cities representing a realistic domestic supply chain. The quantity decreases from 500 to 475 across the stages, reflecting typical losses due to quality control rejections, damaged goods, and transportation attrition. Each event is stored as a Python dictionary with event, location, and qty keys, demonstrating that blockchain blocks can carry structured data payloads.

8.4 Tamper Detection Mechanism

The tamper detection demonstration simulates a real-world attack scenario where a malicious actor attempts to alter quantity data in Block 2:

```
# Simulating tampering attack
sc_chain.chain[2].data = {"event": "Warehouse Stored", "location":
"Bangalore", "qty": 200}

# Detection
print(f'Is blockchain valid after tampering? {sc_chain.is_valid()}')

# Locate the specific tampered block
for i in range(1, len(sc_chain.chain)):
    curr = sc_chain.chain[i]
    prev = sc_chain.chain[i - 1]
    if curr.hash != curr.calculate_hash():
        print(f'Block {curr.index}: HASH MISMATCH  <- data was tampered
here!')
    elif curr.previous_hash != prev.hash:
        print(f'Block {curr.index}: BROKEN LINK   <- chain broken
because of above')
    else:
        print(f'Block {curr.index}: OK')
```

The tamper detection works because modifying sc_chain.chain[2].data changes the block's actual data, but the hash attribute remains the old value (computed from qty=480). When is_valid() calls calculate_hash() on Block 2 with the new data (qty=200), it gets a different hash, creating a mismatch that is immediately detected. The output correctly identifies Block 2 as HASH MISMATCH while Blocks 1, 3, and 4 report OK.

9. TESTING

Testing is a critical phase of software development that ensures the system behaves correctly under various conditions. The testing strategy for this project included unit testing of individual components, integration testing of the complete blockchain system, and customer testing to validate the project against its intended requirements.

9.1 Unit Testing

Unit testing verified that each individual method and class function produces the expected output in isolation.

Test ID	Component	Test Description	Expected Result	Actual Result	Status
UT-01	Block.__init__	Create Block with valid data	Block attributes set correctly, hash computed	All attributes set correctly	PASS
UT-02	Block.calculate_hash	Compute hash of known input	Deterministic 64-char hex string	Consistent 64-char hex returned	PASS
UT-03	Block.calculate_hash	Change data; verify hash changes	Different hash produced	Completely different hash	PASS
UT-04	Blockchain.__init__	Genesis Block created on init	chain[0] is Genesis Block	Genesis Block present at index 0	PASS
UT-05	Blockchain.add_block	Add one block to chain	Chain length increases by 1	Chain length incremented correctly	PASS
UT-06	Blockchain.is_valid	Validate untampered chain	Returns True	True returned	PASS
UT-07	Blockchain.is_valid	Validate after data modification	Returns False	False returned	PASS
UT-08	Blockchain.is_valid	Identify tampered block index	Block 2 flagged as	Block 2: HASH MISMATCH	PASS

Test ID	Component	Test Description	Expected Result	Actual Result	Status
			HASH MISMATCH		

9.2 Integration Testing

Integration testing verified that the Block and Blockchain classes work together correctly as a complete system.

Test ID	Test Scenario	Steps	Expected Result	Status
IT-01	Full chain build and validation	Create chain, add 4 events, call is_valid()	True returned, all blocks linked correctly	PASS
IT-02	Hash chain linkage	Verify chain[1].previous_hash == chain[0].hash	Hashes match across all blocks	PASS
IT-03	Tamper and detect	Modify Block 2 data, call is_valid()	False returned, Block 2 flagged	PASS
IT-04	Print chain output	Call print_chain() on complete chain	All 5 blocks printed with correct data	PASS
IT-05	Genesis Block integrity	Verify Genesis Block has prev_hash '0'	Previous hash is '0'	PASS

9.3 Customer Testing

Customer testing was conducted to verify that the project output matches the expected behavior described in the project requirements and demonstrates the core blockchain concepts effectively.

- The complete blockchain output was reviewed against the expected block data, confirming all five blocks (Genesis + 4 events) are correctly recorded with accurate hashes and chain links.
- The is_valid() function returned True for the untampered chain, confirming correct baseline validation.
- After modifying Block 2's quantity from 480 to 200, is_valid() returned False, confirming tamper detection.

- The block-by-block check correctly identified Block 2 as HASH MISMATCH while reporting Blocks 1, 3, and 4 as OK.
- The VS Code debugpy launcher line in the output was identified as an IDE artifact and does not affect the project's correctness.

Customer testing confirmed that the project output is 100% correct and fully satisfies all stated requirements. No defects or unexpected behaviors were identified.

10. GRAPHICAL USER INTERFACE (GUI) LAYOUT

The current implementation of the Blockchain-Based Supply Chain Management System operates through a command-line interface (CLI). While no graphical user interface has been implemented in this phase, the project includes a web-based front-end demonstration (index.html) that illustrates how a GUI would present the blockchain data to stakeholders.

10.1 Current CLI Interface

The CLI interface produces structured, readable output that effectively communicates the blockchain state. The output is organized into two sections:

- Section 1 – Valid Chain Output: Displays all five blocks with their indices, data, timestamps, previous hashes, and current hashes in a formatted table using separator lines. Concludes with the is_valid() result (True).
- Section 2 – Tamper Detection Output: Displays the tampering scenario, the invalid chain result (False), and the per-block integrity report identifying Block 2 as HASH MISMATCH.

10.2 Web-Based GUI Demonstration (index.html)

The project includes an index.html file that presents a professional web interface titled 'BLOCKCHAIN.SC — Secure Decentralized Supply Chain Ledger'. This interface provides:

- Hero Section: Displays the project title, description, and key metrics (SHA-256 hashing algorithm, 5 blocks in chain, 0% tamper success rate).
- About Section: Explains the blockchain concepts (ledger, SHA-256 hashing, tamper detection, supply chain events) in clear, accessible language for non-technical stakeholders.
- Chain Visualization: Displays the five blocks (Block #0 through Block #4) as visual cards connected by arrows, showing abbreviated hashes and previous hash links.

- Live Demo Section: Shows side-by-side comparison of 'Before Tampering' and 'After Tampering Block 2' terminal output with color-coded text (green for OK, red for HASH MISMATCH).

10.3 Proposed GUI Features for Future Development

A full desktop or web GUI would include the following components:

- Dashboard: Real-time display of chain validity status, total block count, and last event timestamp.
- Add Event Form: A form with fields for event type, location, quantity, and timestamp that appends a new block on submission.
- Chain Explorer: A scrollable, interactive visualization of all blocks with expandable details.
- Tamper Alert Panel: A notification area that highlights invalid blocks in red and displays the specific mismatch details.
- Export Feature: Ability to export the full chain as a JSON or PDF report for audit purposes.

11. EVALUATION

The evaluation assesses the extent to which the project has achieved its stated objectives and compares the implemented system against industry standards and the project requirements.

11.1 Achievement of Objectives

Objective	Achievement	Evidence
Implement Block class with SHA-256 hashing	Fully Achieved	Block.calculate_hash() returns consistent 64-char hex
Implement Blockchain class with validation	Fully Achieved	is_valid() correctly returns True/False
Simulate realistic supply chain scenario	Fully Achieved	4 events across Chennai, Coimbatore, Bangalore, Mumbai
Demonstrate immutability	Fully Achieved	Tamper detected with False result and HASH MISMATCH
Provide readable output	Fully Achieved	Formatted console output with separators and labels
Design modular, extensible architecture	Fully Achieved	Two-class OOP design easily extensible

11.2 Performance Evaluation

The system performs all operations with negligible execution time, completing the full chain creation, validation, and tamper detection in under 1 millisecond on standard hardware. This performance is attributable to SHA-256's computational efficiency for small data inputs and Python's optimized list operations for chain traversal.

11.3 Comparison with Industry Standards

While this project is a simplified simulation, it correctly implements the core cryptographic principles used by enterprise blockchain platforms. The SHA-256 hash pointer mechanism is identical to that used by Bitcoin and Hyperledger Fabric. The primary differences between this simulation and production systems are the absence of

distributed network consensus, digital signatures for transaction authorization, and persistent storage.

11.4 Limitations

- Single-node simulation: The system does not implement peer-to-peer network consensus, which is a fundamental property of true blockchain systems.
- No persistence: The blockchain exists only in memory and is lost when the program terminates. A production system would persist the chain to a database.
- No digital signatures: Transaction authorization is not implemented. In production systems, each event would be digitally signed by the submitting party.
- No proof-of-work: The system does not implement mining or proof-of-work, making it unsuitable for a public, permissionless blockchain scenario.
- Sequential hash re-computation: The tamper detection recalculates hashes sequentially; distributed systems use parallel validation for performance.

12. SNAPSHOTS OF THE PROJECT

This chapter presents the actual output produced by the blockchain.py program, illustrating the system's correct operation through console snapshots.

12.1 Snapshot 1: Valid Blockchain Output

The following snapshot shows the complete output of the five-block supply chain blockchain in its valid, untampered state:

```
========== SUPPLY CHAIN BLOCKCHAIN ==========

==================================================
  Block Number  : 0
  Data          : Genesis Block - Supply Chain Start
  Timestamp     : 2026-04-26 16:19:57.706988
  Previous Hash : 0...
  Current Hash  : 39f66d8cd9a82ed868ec96235dddaf61...
==================================================
  Block Number  : 1
  Data          : {'event': 'Raw Materials Sourced', 'location':
'Chennai', 'qty': 500}
  Timestamp     : 2026-04-26 16:19:57.707052
  Previous Hash : 39f66d8cd9a82ed868ec96235dddaf61...
  Current Hash  : a9af37b6091843aae4c50eec820d92c5...
==================================================
  Block Number  : 2
  Data          : {'event': 'Manufacturing Complete', 'location':
'Coimbatore', 'qty': 480}
  Previous Hash : a9af37b6091843aae4c50eec820d92c5...
  Current Hash  : 90ab56738e07c2129ba957c3fc797a32...
==================================================
  Block Number  : 3
  Data          : {'event': 'Warehouse Stored', 'location': 'Bangalore',
'qty': 480}
  Previous Hash : 90ab56738e07c2129ba957c3fc797a32...
  Current Hash  : d24a4791bd91fcee00e4873997abc664...
==================================================
  Block Number  : 4
  Data          : {'event': 'Delivered to Retailer', 'location':
'Mumbai', 'qty': 475}
  Previous Hash : d24a4791bd91fcee00e4873997abc664...
  Current Hash  : 10c8e7414d1c991e850ad7f8868202de...
==================================================

✅ Is blockchain valid? True
```

12.2 Snapshot 2: Tamper Detection Output

The following snapshot shows the output after Block 2's quantity is changed from 480 to 200, demonstrating real-time tamper detection:

```
========== TAMPERING WITH BLOCK 2 ==========
Hacker changes qty from 480 → 200 in Block 2...

❌ Is blockchain valid after tampering? False

--- Checking each block ---
  Block 1: OK
  Block 2: HASH MISMATCH  ← data was tampered here!
  Block 3: OK
  Block 4: OK
```

12.3 Snapshot 3: Chain Integrity Analysis

The snapshots clearly demonstrate the two-phase validation process: Phase 1 shows a fully valid chain with all hashes matching and all chain links intact. Phase 2 shows the immediate detection of data modification at Block 2, with the system precisely identifying the tampered block while correctly reporting all other blocks as OK.

The hash values shown in the snapshots are the actual SHA-256 outputs computed by Python's hashlib.sha256() function. The first 40 characters are displayed due to console formatting (truncated with ...), though the actual stored hashes are the full 64-character hexadecimal strings.

13. CONCLUSIONS

This project successfully demonstrates the application of blockchain technology to supply chain management through the design, implementation, and testing of a Python-based blockchain simulation. The following key conclusions can be drawn from the project:

13.1 Technical Conclusions

- SHA-256 cryptographic hashing provides an effective and computationally efficient mechanism for ensuring data integrity in blockchain applications. The 64-character hexadecimal fingerprint is unique to each block's content, making unauthorized modification instantly detectable.
- The hash pointer linkage mechanism creates a tamper-evident chain where modification of any single block breaks all subsequent chain links, ensuring that fraud cannot be introduced silently without detection.
- Python's standard library (hashlib and datetime) provides all necessary tools for implementing a functional blockchain prototype without any external dependencies.
- Object-oriented programming principles, specifically class-based encapsulation and separation of concerns, are well-suited to modeling blockchain data structures.

13.2 Business Conclusions

- Blockchain technology offers a compelling solution to the transparency, trust, and accountability challenges faced by modern supply chains.
- An immutable supply chain ledger enables all stakeholders — suppliers, manufacturers, warehouses, and retailers — to share a single source of truth, reducing disputes and costly reconciliation processes.
- The tamper detection capability demonstrated in this project could prevent significant financial losses from supply chain fraud in real-world deployments.

13.3 Learning Outcomes Achieved

- Gained hands-on experience with SHA-256 cryptographic hashing and its application in data integrity verification.
- Developed proficiency in Python object-oriented programming through the design and implementation of the Block and Blockchain classes.
- Acquired understanding of blockchain fundamentals applicable to IBM Blockchain Platform and Hyperledger Fabric enterprise deployments.
- Completed IBM SkillsBuild programme requirements through practical application of cloud computing and blockchain concepts.

14. FURTHER DEVELOPMENT OR RESEARCH

The current implementation provides a solid foundation for a more comprehensive blockchain supply chain system. Several directions for future development and research have been identified:

14.1 Peer-to-Peer Network Implementation

The most significant enhancement would be implementing a genuine peer-to-peer network where multiple nodes maintain copies of the blockchain. Python's socket library or a framework such as Flask or FastAPI could be used to create HTTP-based node communication. A consensus algorithm (such as Proof of Work, Proof of Stake, or Practical Byzantine Fault Tolerance) would be implemented to achieve agreement on the valid chain state across nodes.

14.2 Persistent Storage Integration

Replacing the in-memory chain list with a persistent database (SQLite for development, PostgreSQL or MongoDB for production) would enable the blockchain to survive application restarts. Each block's attributes would be stored as a database record, with the chain rebuilt from stored data on application launch.

14.3 Digital Signature Authentication

Implementing digital signatures using Python's cryptography library would add transaction authentication to the system. Each supply chain participant would have a public-private key pair. New blocks would be signed with the submitter's private key, allowing any participant to verify the block's authenticity using the corresponding public key.

14.4 Smart Contract Integration

Smart contracts — self-executing code stored on the blockchain — could automate supply chain processes such as automatic payment release upon delivery confirmation, quality control checkpoint enforcement, and regulatory compliance verification.

14.5 IBM Blockchain Platform Integration

The simulation could be extended to integrate with IBM Blockchain Platform (based on Hyperledger Fabric) to create an enterprise-grade deployment. IBM's platform provides managed nodes, policy-based access control, and built-in integration with IBM Cloud services, making it suitable for production supply chain deployments.

14.6 Machine Learning for Anomaly Detection

Integrating machine learning algorithms could enhance the system's ability to detect not only direct data tampering but also subtle patterns that may indicate fraudulent activity, such as unusual quantity fluctuations or suspicious location sequences. Python's scikit-learn library provides accessible ML tools for anomaly detection.

14.7 IoT Sensor Integration

Connecting IoT sensors (temperature, weight, GPS) to automatically record supply chain events would eliminate manual data entry and further reduce fraud opportunities. Each sensor reading would automatically trigger a new block creation, creating a real-time, sensor-verified supply chain record.

16.2 Appendix B: IBM SkillsBuild Programme Details

This project was completed as part of the IBM SkillsBuild Internship Programme for the academic year 2025–2026. The IBM SkillsBuild platform provides free access to digital learning resources, including courses on cloud computing, artificial intelligence, cybersecurity, and blockchain technology. Students completing the programme earn IBM digital badges that are verifiable credentials on the Credly platform.

16.3 Appendix C: Glossary of Terms

Term	Definition
Blockchain	A distributed ledger technology where records are stored in cryptographically linked blocks
Genesis Block	The first block in a blockchain, with no preceding block (previous hash set to '0')
SHA-256	A 256-bit cryptographic hash function that produces a unique 64-character hexadecimal digest
Hash	A fixed-length digital fingerprint produced by a cryptographic hash function
Hash Pointer	A link between blocks containing the hash of the preceding block
Immutability	The property that once data is recorded on a blockchain, it cannot be altered without detection
Tamper Detection	The ability to identify unauthorized modifications to blockchain data
Consensus	The mechanism by which distributed blockchain nodes agree on the valid state of the chain
Distributed Ledger	A record-keeping system where identical copies are maintained by multiple participants
Smart Contract	Self-executing code stored on a blockchain that automatically enforces predefined conditions
Hyperledger Fabric	An enterprise-grade permissioned blockchain framework developed under the Linux Foundation
